Assignment T-test

Date: 05/05/2020 Name: D.Saravanan

TTest test the null hypothesis H_0 against the alternative hypothesis H_1.

For univariate samples, TTest performs a Student t test. The test statistic is assumed to follow a StudentTDistribution [df].

The degrees of freedom df, used to specify the distribution of the test statistic, depend on the sample size, number of samples, and in the case of two univariate samples, the results of a test for equal variances.

For the TTest, a cutoff α is chosen such that H_0 is rejected only if $p < \alpha$. The value of α used for the "TestConclusion" and "ShortTestConclusion" properties is controlled by the SignificanceLevel option. This value α is also used in diagnostic tests of assumptions, including tests for normality, equal variance, and symmetry. By default, α is set to 0.05.

1. Two sets of ten students selected at random from a college were taken. One set was given memory test as they were and the other was given the memory test after two weeks of training and the scores are given below.

Set A:	10	8	7	9	8	10	9	6	7	8
Set B:	12	8	8	10	8	11	9	8	9	9

Do you think there is a significant effect due to training?

Solution:

Set A:

Mean:

$$\bar{x}_1 = \frac{\sum_{i=1}^{n1} x_{1i}}{n1} = \frac{10+8+7+9+8+10+9+6+7+8}{10} = 8.2$$

Variance:

$$s_1^2 = \frac{\sum_{i=1}^{n1} (x_{1i} - \bar{x_1})^2}{n1 - 1} = \frac{\sum_{i=1}^{10} (x_{1i} - 8.2)^2}{10 - 1} = 1.73333$$

Standard Deviation:

$$s_1 = \sqrt{\frac{\sum_{i=1}^{n1} (x_{1i} - \bar{x_1})^2}{n1 - 1}} = \sqrt{\frac{\sum_{i=1}^{10} (x_{1i} - 8.2)^2}{10 - 1}} = \sqrt{1.73333} = 1.31656$$

Set B:

Mean:

$$\bar{x}_2 = \frac{\sum_{i=1}^{n2} x_{2i}}{n2} = \frac{12+8+8+10+8+11+9+8+9+9}{10} = 9.2$$

Variance:

$$s_2^2 = \frac{\sum_{i=1}^{n2} (x_{2i} - \bar{x_2})^2}{n2 - 1} = \frac{\sum_{i=1}^{10} (x_{2i} - 9.2)^2}{10 - 1} = 1.95556$$

Standard Deviation:

$$s_2 = \sqrt{\frac{\sum_{i=1}^{n2}(x_{2i} - \bar{x}_2)^2}{n2 - 1}} = \sqrt{\frac{\sum_{i=1}^{10}(x_{2i} - 9.2)^2}{10 - 1}} = \sqrt{1.95556} = 1.39841$$

Calculation of $s1/s2$:

$$\frac{s_1}{s_2} = \frac{1.31656}{1.39841} = 0.94147$$

Test statistic:

$$T = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{s_1^2/n1 + s_2^2/n2}}$$

where $n1$ and $n2$ are the sample sizes, $\bar{x}_1$ and $\bar{x}_2$ are the sample means, and s_1^2 and s_2^2 are the sample variances. If equal variances are assumed $(0.5 < s1/s2 < 2)$, then the formula reduces to:

$$T = \frac{\bar{x}_1 - \bar{x}_2}{s_p\sqrt{1/n1 + 1/n2}}$$

where

$$s_p^2 = \frac{(n1 - 1)s_1^2 + (n2 - 1)s_2^2}{n1 + n2 - 2}$$

Calculation of s_p:

$$s_p = \sqrt{\frac{(10 - 1) \times 1.31656^2 + (10 - 1) \times 1.39841^2}{10 + 10 - 2}} = 1.35810$$

Calculation of T statistic:

$$T = \frac{8.2 - 9.2}{1.35810 \times \sqrt{1/10 + 1/10}} = -1.64646$$

Calculation of Standard Error:

$$S.E = s_p\sqrt{1/n1 + 1/n2} = 1.35810 \times \sqrt{1/10 + 1/10} = 0.60736$$

Program:

```
#!/usr/bin/env python3
import numpy as np

2. A group of 5 patients treated with medicine A weighs 42, 29, 48, 60 and 41 kg. A second group of 7 patients from the same hospital treated with medicine B weighs 38, 42, 56, 64, 68, 69 and 62 kg. Do you agree with the claim that medicine B increases weight significantly.

Null hypothesis: $H_0 : \mu 1 = \mu 2$
Alternative hypothesis: $H_1 : \mu 1 \neq \mu 2$

Medicine A:

Mean:

$$\bar{x}_1 = \frac{\sum_{i=1}^{n1} x_{1i}}{n1} = \frac{42 + 29 + 48 + 60 + 41}{5} = 44.0$$

Variance:

$$s_1^2 = \frac{\sum_{i=1}^{n1} (x_{1i} - \bar{x_1})^2}{n1 - 1} = \frac{\sum_{i=1}^{5} (x_{1i} - 44.0)^2}{5 - 1} = 127.5$$

Standard Deviation:

$$s_1 = \sqrt{\frac{\sum_{i=1}^{n1} (x_{1i} - \bar{x_1})^2}{n1 - 1}} = \sqrt{\frac{\sum_{i=1}^{5} (x_{1i} - 44.0)^2}{5 - 1}} = \sqrt{127.5} = 11.29159$$

Medicine B:

Mean:

$$\bar{x}_1 = \frac{\sum_{i=1}^{n1} x_{1i}}{n1} = \frac{38 + 42 + 56 + 64 + 68 + 69 + 62}{7} = 57.0$$

Variance:

$$s_1^2 = \frac{\sum_{i=1}^{n1} (x_{1i} - \bar{x_1})^2}{n1 - 1} = \frac{\sum_{i=1}^{7} (x_{1i} - 57.0)^2}{7 - 1} = 154.3$$

Standard Deviation:

$$s_1 = \sqrt{\frac{\sum_{i=1}^{n1} (x_{1i} - \bar{x_1})^2}{n1 - 1}} = \sqrt{\frac{\sum_{i=1}^{7} (x_{1i} - 57.0)^2}{7 - 1}} = \sqrt{154.3} = 12.42310$$

Calculation of $s1/s2$:

$$\frac{s_1}{s_2} = \frac{11.29159}{12.42310} = 0.90892$$

Test statistic:

$$T = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{s_1^2/n1 + s_2^2/n2}}$$

If equal variances are assumed $(0.5 < s1/s2 < 2)$, then the formula reduces to:

$$T = \frac{\bar{x}_1 - \bar{x}_2}{s_p\sqrt{1/n1 + 1/n2}}$$

where

$$s_p^2 = \frac{(n1-1)s_1^2 + (n2-1)s_2^2}{n1+n2-2}$$

Calculation of s_p:

$$s_p = \sqrt{\frac{(5-1)\times 11.29159^2 + (7-1)\times 12.42310^2}{5+7-2}} = 11.98332$$

Calculation of T statistic:

$$T = \frac{44.0 - 57.0}{11.98332 \times \sqrt{1/5+1/7}} = -1.85272$$

Calculation of Standard Error:

$$S.E = s_p\sqrt{1/n1 + 1/n2} = 11.98332 \times \sqrt{1/5+1/7} = 7.01671$$

Program:

```
#!/usr/bin/env python3

Output:

```
__________Two-sample T-test for unpaired data__________
```

```
Sample 1:
     Number of Observations = 5
     Mean = 44.00000
     Standard Deviation = 10.09950
     Standard Error of the Mean = 4.51664

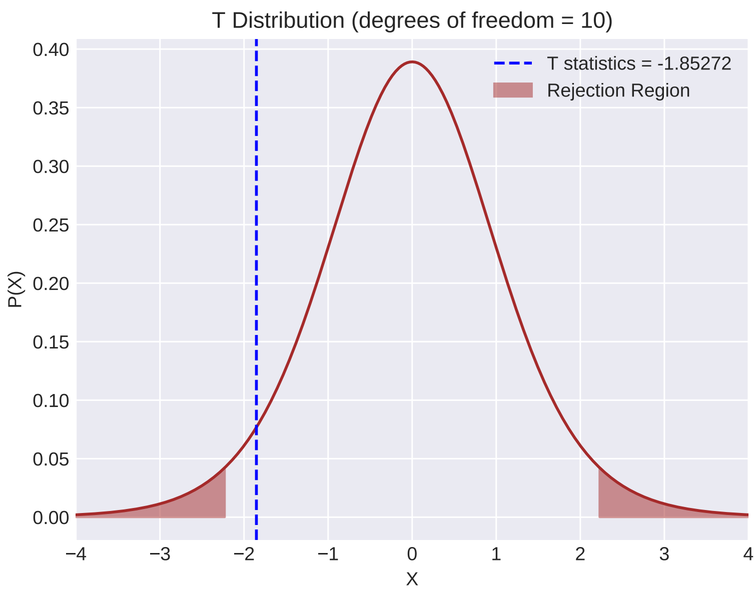
Sample 2:
     Number of Observations = 7
     Mean = 57.00000
     Standard Deviation = 11.50155
     Standard Error of the Mean = 4.34718

T statistics: -1.85272

Critical values are -2.22814, 2.22814
Fail to reject the Null hypothesis.

p-value: 0.09363
Fail to reject the Null hypothesis.

Standard Error: 6.41885
Confidence Interval: [-27.30208861   1.30208861]
```



3. Samples of two types of electric bulbs were tested for length of life and the following data were obtained

	Type I	Type II
No. of Samples:	8	7
Mean (hours):	1134	1024
SD (hours):	35	40

Test at 5 percent level, whether the difference in sample mean is significant.

Null hypothesis: $H_0 : \mu1 = \mu2$
Alternative hypothesis: $H_1 : \mu1 \neq \mu2$

Type I:
    Mean = 1134

Variance = 1225
Standard Deviation = 35

Type II:
Mean = 1024
Variance = 1600
Standard Deviation = 40

Calculation of $s1/s2$:

$$\frac{s_1}{s_2} = \frac{35}{40} = 0.875$$

Test statistic:

$$T = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{s_1^2/n1 + s_2^2/n2}}$$

where $n1$ and $n2$ are the sample sizes, $\bar{x}_1$ and $\bar{x}_2$ are the sample means, and s_1^2 and s_2^2 are the sample variances. If equal variances are assumed $(0.5 < s1/s2 < 2)$, then the formula reduces to:

$$T = \frac{\bar{x}_1 - \bar{x}_2}{s_p\sqrt{1/n1 + 1/n2}}$$

where

$$s_p^2 = \frac{(n1-1)s_1^2 + (n2-1)s_2^2}{n1 + n2 - 2}$$

Calculation of s_p:

$$s_p = \sqrt{\frac{(8-1) \times 35^2 + (7-1) \times 40^2}{8 + 7 - 2}} = 37.39087$$

Calculation of T statistic:

$$T = \frac{1134 - 1024}{37.39087 \times \sqrt{1/8 + 1/7}} = 5.68428$$

Calculation of Standard Error:

$$S.E = s_p\sqrt{1/n1 + 1/n2} = 37.39087 \times \sqrt{1/8 + 1/7} = 19.35161$$
